Abstract We present a general formulation for incompressible fluid flow analysis using the finite element method. The necessary stabilization for dealing with convective effects and the incompressibility condition are introduced via the Finite Calculus method using a matrix form of the stabilization parameters. This allows to model a wide range of fluid flow problems for low and high Reynolds numbers flows without introducing a turbulence model. Examples of application to the analysis of incompressible flows with moderate and large Reynolds numbers are presented.

Keywords Stabilized formulation · Incompressible fluid · Finite calculus · Finite element method · High Reynolds numbers · Turbulence model

1 Introduction

Much effort has been spent in developing the so called stabilized numerical methods overcoming the two main sources of instability in incompressible flow analysis, namely those originated by the high values of the convective terms and those induced by the difficulty in satisfying the incompressibility condition.

The solution of above problems in the context of the finite element method (FEM) has been attempted in a number of ways. The first attempts to correct the underdiffusive character of the Galerkin FEM for high convection flows were based in adding some kind of artificial viscosity terms to the standard Galerkin equations [1, 2].

A popular way to overcome the problems with the incompressibility constraint is by introducing a pseudo-compressibility in the flow and using implicit and explicit algorithms developed for this kind of problems such as artificial compressibility schemes [3–5] and preconditioning techniques [6]. State of the art FEM schemes for fluid flow analysis with good stabilization properties for the convective and incompressibility terms are based in Petrov-Galerkin (PG) techniques. The background of PG methods are the non-centred (upwind) schemes for computing the first derivatives of the convective operator in finite difference and finite volume methods [7, 8]. A general class of stabilized PG FEM has been recently developed where the standard Galerkin variational form of the momentum and mass balance equations is extended with adequate residual-based terms in order to achieve a stabilized numerical scheme. References [9–30] list some of the more popular stabilized FEM of this kind. A review of many of these methods can be found in [1, 31].

In this paper a stabilized FEM for incompressible flows is derived via a finite calculus (FIC) approach [32, 33]. The FIC method is based in invoking the balance of fluxes in a fluid domain of finite size. This introduces naturally additional terms in the classical differential equations of momentum and mass balance of infinitesimal fluid mechanics which are a function of characteristic length dimensions related to the element size in the discretized problem. The FIC terms in the modified governing equations provide the necessary stabilization to the discrete equations obtained via the standard Galerkin FEM. The FIC/FEM formulation allows to use low order finite elements (such as linear triangles and tetrahedra) with equal order approximations for the velocity and pressure variables.

The FIC/FEM formulation has proven to be very effective for the solution of a wide class of problems, such as convection-diffusion [32–39] and convection-diffusion-reaction [40–42] involving arbitrary high gradients, incompressible flow problems accounting for free surface effects and fluid–structure interaction situations [32, 33, 43–51] and quasi and fully incompressible problems in solid mechanics [52, 53].

The FIC equations for incompressible flow derived in previous works of the authors assumed that the dimensions of the domain where the momentum conservation law was enforced remain the same independently of the direction along which balance of momentum is imposed. As a consequence,
The FIC governing equations for a viscous incompressible fluid can be written in an Eulerian frame of reference as the same characteristic dimensions which can be grouped in a characteristic distance vector. In this paper, a refined FIC formulation with matrix stabilizing terms for incompressible flows at low and high Reynolds numbers introduces a matrix form of the characteristic distances and of the corresponding FIC terms which have better intrinsic stabilization properties.

The idea of a matrix form of the stabilization parameters is close to the element-matrix-based and element-vector-based stabilization parameters proposed in [54] where different intrinsic time parameters were defined separately for each degree of freedom of the equation system. Stabilized FEM have been successfully used in the past to solve a wide range of fluid mechanics problems. The intrinsic dissipative properties of the stabilization terms (which can interpreted as an additional viscosity) typically suffice to yield good results for low and moderate values of the Reynolds number (Re). For high values of Re most stabilized FEM fail to provide physically meaningful results and the numerical solution is often unstable or inaccurate. The introduction of a turbulence model is mandatory in order to obtain meaningful results in these cases.

The relationship between the additional dissipation introduced by the turbulence model and the intrinsic dissipative properties of stabilized FEM is an open topic which is attracting increasing attention in the CFD community. It is clear that both remedies (the turbulence model and the stabilization terms) play a similar role in the numerical solution, i.e. that of ensuring a solution which is “physically sound” and as accurate as possible.

It is our belief that the matrix stabilization terms introduced by the FIC/FEM formulation here presented allow to overcome the numerical instabilities due to the convective sharp gradients without introducing any transverse dissipative properties of stabilized FEM is an open topic which is attracting increasing attention in the CFD community. It is clear that both remedies (the turbulence model and the stabilization terms) play a similar role in the numerical solution, i.e. that of ensuring a solution which is “physically sound” and as accurate as possible.

It is clear that both remedies (the turbulence model and the stabilization terms) play a similar role in the numerical solution, i.e. that of ensuring a solution which is “physically sound” and as accurate as possible.

2 General FIC equations for viscous incompressible flow

The FIC governing equations for a viscous incompressible fluid can be written in an Eulerian frame of reference as

**Momentum**

\[
\frac{1}{2} h_{ij} \frac{\partial r_m}{\partial x_j} = 0 \quad \text{in } \Omega \quad \text{no sum in } i.
\]

**Mass balance**

\[
r = \frac{1}{2} h_{ij} \frac{\partial r_n}{\partial x_j} = 0 \quad \text{in } \Omega,
\]

where

\[
r_m = \rho \left( \frac{\partial u_i}{\partial t} + u_j \frac{\partial u_i}{\partial x_j} \right) + \frac{\partial p}{\partial x_i} - \delta_{ij} \frac{\partial s_{ij}}{\partial x_j} - b_i
\]

\[
r = \frac{\partial u_i}{\partial x_j} i, \ j = 1, n_d.
\]

Above \( \Omega \) is the analysis domain, \( n_d \) is the number of space dimensions (\( n_d = 2 \) for 2D problems), \( u_i \) is the velocity along the \( i \)th global axis, \( \rho \) is the (constant) density of the fluid, \( p \) is the absolute pressure (defined positive in compression), \( b_i \) are the body forces and \( s_{ij} \) are the viscous deviatoric stresses related to the viscosity \( \mu \) by the standard expression

\[
s_{ij} = 2\mu \left( \delta_{ij} - \frac{1}{3} \frac{\partial u_k}{\partial x_k} \right),
\]

where \( \delta_{ij} \) is the Kronecker delta and the strain rates \( \dot{e}_{ij} \) are

\[
\dot{e}_{ij} = \frac{1}{2} \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right).
\]

The FIC boundary conditions are

\[
n \sigma_{ij} - t_i + \frac{1}{2} h_{ij} n_j r_m = 0 \quad \text{on } \Gamma_t \quad \text{no sum in } i,
\]

\[
u - u_i^p = 0 \quad \text{on } \Gamma_u
\]

and the initial condition is \( u_i = u_i^0 \) for \( t = t_0 \).

The \( h_{ij} \) and \( h_j \) are characteristic distances of the domain where balance of momentum and mass is enforced. In Eqs. (1) and (2) these lengths define the domain where equilibrium of boundary tractions is established \([32]\). In the discretized problem the characteristic distances become of the order of the typical element dimensions. Note that by making these distances equal to zero the standard infinitesimal form of the fluid mechanics equations is recovered \([1, 7, 31]\).

Equations (1)–(6) are the starting point for deriving stabilized FEM for solving the incompressible Navier–Stokes equations. The underlined FIC terms in Eq. (1) are essential to overcome the numerical instabilities due to the convective terms in the momentum equations, whereas underlined terms in Eq. (2) take care of the instabilities due to the compressibility constraint. An interesting feature of the FIC formulation is that it allows to use equal order interpolation for the velocity and pressure variables \([43–53]\).
Remark 1  In previous work of the authors the characteristic distances in the momentum equations had a vector form, i.e. the FIC momentum equations were written as

\[ r_i - \frac{1}{2} h_i \frac{\partial r_i}{\partial x_j} = 0 \]  

(7a)

or

\[ r_i - \frac{1}{2} h^T \nabla r_i = 0, \]

(7b)

where (for 2D problems) \( h = [h_1, h_2]^T \) is the characteristic length vector [32, 33, 43].

The difference of Eqs. (7) with Eq. (1) is that the characteristic distances have now a matrix form, i.e. the expanded form of the momentum equations (1) is (for 2D problems)

\[ r_i - \frac{1}{2} (h_1 \frac{\partial r_i}{\partial x_1} + h_2 \frac{\partial r_i}{\partial x_2}) = 0 \]

(8)

The rationale of Eqs. (8) is briefly explained in the Appendix. The matrix of stabilization parameters \( S \) is defined as (for 2D problems)

\[ S = \begin{bmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{bmatrix} \]

(9)

Remark 2  Note that the characteristic distances in the FIC mass conservation equation (2) have a vector form. As mentioned above distances \( h_1 \) and \( h_2 \) in Eq. (2) (for 2D problems) denote the dimensions of the domain where balance of mass is globally enforced (see Appendix). This is a basic difference with traditional methods where mass balance law is applied along each global coordinate direction.

2.1 Stabilized integral forms

From the momentum equations it can be obtained [43, 45]

\[ \frac{\partial r_d}{\partial x_i} \approx \frac{h_{ii}}{2a_i} \frac{\partial r_{mi}}{\partial x_i}, \]  

(10a)

where

\[ a_i = \frac{2\mu}{3} + \frac{\rho u_i h_{ii}}{2}, \]  

(10b)

Substituting Eq. (10a) into Eq. (2) and retaining the terms involving the derivatives of \( r_{mi} \) with respect to \( x_i \) only, leads to the following alternative expression for the stabilized mass balance equation

\[ r_d - \sum_{i=1}^{n_d} \tau_i \frac{\partial r_{mi}}{\partial x_i} = 0 \]

(11)

with \( \tau_i \)’s in Eq. (11) when multiplied by the density are equivalent to the intrinsic time parameters, seen extensively in the stabilization literature. The interest of Eq. (11) is that it introduces the first space derivatives of the momentum equations into the mass balance equation. These terms have intrinsic good stability properties as explained next.

The weighted residual form of the momentum and mass balance equations [Eqs. (1), (11)] is written as

\[ \int_{\Omega} \delta u_i \left[ r_{mi} - \frac{h_{ij}}{2} \frac{\partial r_{mj}}{\partial x_j} \right] d\Omega \]

\[ + \int_{\Gamma_r} \delta u_i \left( \sigma_{ij} n_j - t_i + \frac{h_{ij}}{2} n_j r_{mj} \right) d\Gamma = 0 \]  

(13)

\[ \int_{\Omega} q \left[ r_d - \sum_{i=1}^{n_d} \tau_i \frac{\partial r_{mi}}{\partial x_i} \right] d\Omega = 0, \]

(14)

where \( \delta u_i \) and \( q \) are arbitrary weighting functions representing virtual velocities and virtual pressure fields. Integrating by parts the \( r_{mi} \) terms in Eqs. (13) and (14) leads to
FIC/FEM formulation with matrix stabilizing terms for incompressible flows at low and high Reynolds numbers

\[ \int_{\Omega_1} \sum_{i=1}^{k} r_i n_i r_{m_i} \, d\Omega = 0. \]  

(15a)

In the derivation of the viscous term in Eq. (16a) we have used the following identity holding for incompressible fluids (prior to the integration by parts)

\[ \partial_s \varepsilon_{ij} \partial x_j = 2 \mu \partial u_i \partial x_j. \]  

(17)

2.2 Convective and pressure gradient projections

The computation of the residual terms are simplified if we introduce the convective and pressure gradient projections \( c_i \) and \( \pi_i \), respectively, defined as

\[ c_i = r_{m_i} - \rho u_j \frac{\partial u_i}{\partial x_j}, \]

\[ \pi_i = r_{m_i} - \frac{\partial p}{\partial x_i}. \]  

(18)

We can express \( r_{m_i} \) in Eqs. (16a) and (16b) in terms of \( c_i \) and \( \pi_i \), respectively which then become additional variables. The system of integral equations is now augmented in the necessary number of equations by imposing that the residual \( r_{m_i} \) vanishes (in average sense) for both forms given by Eqs. (18). This gives the final system of governing equations as:

\[ \int_{\Omega} \left[ \delta u_i \left( \frac{\partial u_i}{\partial t} + u_j \frac{\partial u_i}{\partial x_j} \right) + \frac{\partial \delta u_i}{\partial x_j} \left( \mu \frac{\partial u_i}{\partial x_j} - \delta_{ij} p \right) \right] \, d\Omega \]

\[ - \int_{\Gamma} \left[ \sum_{i=1}^{k} r_i n_i r_{m_i} \right] \, d\Gamma = 0. \]  

(16a)

\[ \int_{\Omega} \left[ q \frac{\partial u_i}{\partial x_i} + \sum_{i=1}^{k} \tau_i q r_{m_i} \right] \, d\Omega = 0. \]  

(16b)
where the sum goes over the number of nodes of each element \( n \) \((n = 3/4 \) for triangles/tetrahedra\)), \((\cdot)^k\) denotes the nodal variables and \( N^k \) are the linear shape functions \([1]\).

Substituting the approximations (23) into Eqs. (19)–(22) and choosing the Galerkin form with \( \delta u_i = q = \delta \pi_i = \delta N^k = 0 \) leads to the following system of discretized equations:

\[
\begin{align}
M^{ab}_{ij} &= \left( \int_{\Omega} \rho N^a N^b \delta \Omega \right) \delta_{ij}, \quad A^{ab}_{ij} = \left( \int_{\Omega} \rho N^a (\mathbf{u} \nabla N^b) \delta \Omega \right) \delta_{ij}, \\
K_{ij}^{ab} &= \left( \int_{\Omega} \mu \nabla^T N^a \nabla N^b \delta \Omega \right) \delta_{ij}, \quad \mathbf{V} = \left[ \frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_3} \right]^T, \\
\hat{K}_{ij}^{ab} &= \frac{1}{2} \left( \int_{\Omega} h_{ij} \frac{\partial N^a}{\partial x_j} (\mathbf{u} \nabla N^b) \delta \Omega \right) \delta_{ij}, \quad G^{ab}_{ij} = \left( \int_{\Omega} \frac{\partial N^a}{\partial x_i} N^b \delta \Omega \right), \\
C &= \begin{bmatrix} C_1 \\ C_2 \\ C_3 \end{bmatrix}, \quad \mathbf{C}^{ab} = \frac{1}{2} \left( \int_{\Omega} h_{ij} \frac{\partial N^a}{\partial x_j} N^b \delta \Omega \right), \\
\hat{\mathbf{F}} = \left( \nabla^T N^a \right) [\tau] \nabla N^b \delta \Omega, \quad [\tau] = \begin{bmatrix} \tau_1 & 0 & 0 \\ 0 & \tau_2 & 0 \\ 0 & 0 & \tau_3 \end{bmatrix}, \\
\mathbf{Q} &= \begin{bmatrix} Q_1 \\ Q_2 \\ Q_3 \end{bmatrix}, \quad \mathbf{Q}^{ab}_{i} = \int_{\Omega} \tau_i \frac{\partial N^a}{\partial x_i} N^b \delta \Omega \quad \text{no sum in } i.
\end{align}
\]

with \( i, j, k = 1, n_d \). In Eqs. (21) and (22) \( \delta c_i \) and \( \delta \pi_i \) are appropriate weighting functions and the \( \rho \) and \( \tau \) weights are introduced for convenience.

We note that accounting for the convective and pressure gradient projections enforces the consistency of the formulation as it ensures that the stabilization terms in Eqs. (19) and (20) have a residual form which vanishes for the "exact" solution. Neglecting these terms can reduce the accuracy of the numerical solution and it makes the formulation more sensitive to the value of the stabilization parameters as shown in references \([51–53]\).

### 3 Finite element discretization

We choose \( C^0 \) continuous linear interpolations of the velocities, the pressure, the convection projections \( c_i \) and the pressure gradient projections \( \pi_i \) over 3-noded triangles (2D) and 4-noded tetrahedra (3D). The linear interpolations are written as

\[
\begin{align}
& u_i = N^k \bar{u}^k, \quad p = N^k \bar{p}^k, \\
& c_i = N^k \bar{c}_l, \quad \pi_i = N^k \bar{\pi}_l,
\end{align}
\]

for 2D problems)

\[
\begin{align}
& M^{ab}_{ij} = \left( \int_{\Omega} \rho N^a N^b \delta \Omega \right) \delta_{ij}, \quad A^{ab}_{ij} = \left( \int_{\Omega} \rho N^a (\mathbf{u} \nabla N^b) \delta \Omega \right) \delta_{ij}, \\
& K_{ij}^{ab} = \left( \int_{\Omega} \mu \nabla^T N^a \nabla N^b \delta \Omega \right) \delta_{ij}, \quad \mathbf{V} = \left[ \frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \frac{\partial}{\partial x_3} \right]^T, \\
& \hat{K}_{ij}^{ab} = \frac{1}{2} \left( \int_{\Omega} h_{ij} \frac{\partial N^a}{\partial x_j} (\mathbf{u} \nabla N^b) \delta \Omega \right) \delta_{ij}, \quad G^{ab}_{ij} = \left( \int_{\Omega} \frac{\partial N^a}{\partial x_i} N^b \delta \Omega \right), \\
& C = \begin{bmatrix} C_1 \\ C_2 \\ C_3 \end{bmatrix}, \quad \mathbf{C}^{ab} = \frac{1}{2} \left( \int_{\Omega} h_{ij} \frac{\partial N^a}{\partial x_j} N^b \delta \Omega \right), \\
& \hat{\mathbf{F}} = \left( \nabla^T N^a \right) [\tau] \nabla N^b \delta \Omega, \quad [\tau] = \begin{bmatrix} \tau_1 & 0 & 0 \\ 0 & \tau_2 & 0 \\ 0 & 0 & \tau_3 \end{bmatrix}, \\
& \mathbf{Q} = \begin{bmatrix} Q_1 \\ Q_2 \\ Q_3 \end{bmatrix}, \quad \mathbf{Q}^{ab}_{i} = \int_{\Omega} \tau_i \frac{\partial N^a}{\partial x_i} N^b \delta \Omega \quad \text{no sum in } i.
\end{align}
\]

where \( H = A + K + K \).

If we denote the node indexes with superscripts \( a, b \), the space indices with subscripts \( i, j \), the element contributions to the components of the arrays involved in these equations are \((i, j = 1, 3 \) for 3D problems)
\[ C = [C_1, C_2, C_3], \quad \dot{C}_{1b} = \dot{C}_{2b} = \dot{C}_{3b} = \int_{\Omega} \rho^2 N^a (u^T \nabla N^b) d\Omega \]

\[ \dot{M}_{ij}^{ab} = \left( \int_{\Omega} \tau_i N^a N^b d\Omega \right) \delta_{ij} \quad \hat{f}_i^{ab} = \int_{\Omega} N^a f_i d\Omega + \int_{\Gamma} N^a t_i d\Gamma. \quad (27) \]

It is understood that all the arrays are matrices (except \( f \) which is a vector) whose components are obtained by grouping together the left indices in the previous expressions (\( a \) and possibly \( i \)) and the right indices (\( b \) and possibly \( j \)).

3.1 Transient solution scheme

The solution in time of the system of Eqs. (24) can be written in general form as

\[ M \frac{1}{\Delta t} (\ddot{u}^{n+1} - \ddot{u}^n) + H^{n+\theta} \ddot{u}^{n+\theta} - G \ddot{p}^{n+\theta} + C^{n+\theta} \bar{c}^{n+\theta} = \rho^n \theta^n \]

\[ G^T \dddot{u}^{n+\theta} + \dot{L}^{n+\theta} \dddot{p}^{n+\theta} + Q \dddot{\pi}^{n+\theta} = 0 \]

\[ \dot{C}^{n+\theta} \dddot{u}^{n+\theta} + \dot{M}^{n+\theta} \dddot{\pi}^{n+\theta} = 0 \]

where \( H^{n+\theta} = H (u^{n+\theta}) \), etc and the parameter \( \theta \in [0, 1] \). The direct monolithic solution of Eqs. (27) is possible using an adequate iterative scheme [52, 53]. However, in our work we have used the fractional step method described next.

4 Fractional step method

A fractional step scheme is derived by splitting the discretized momentum equation (27a) into the two following equations

\[ \frac{1}{\rho} L \quad \text{with} \quad L^{ab} = \int_{\Omega} \nabla^T N^a \nabla N^b d\Omega, \quad (31) \]

Register for free at https://www.scipedia.com to download the version without the watermark.
Step 1  Eq. (28a) is linearized as
\[
\frac{\Delta t}{2} \left[ \vec{H}^{n+\theta} \vec{u}^{n+\theta} - \alpha \vec{G} \vec{p}^{n} + \vec{C}^{n+\theta} \vec{c}^{n} \right] = \vec{T}^{n+\theta},
\]  
(32)
where \( \vec{u}^{n+\theta} = \theta \vec{u}^{n+1} + (1 - \theta) \vec{u}^{n} \), \( \vec{H}^{n+\theta} = \vec{H} \left( \vec{u}^{n+\theta} \right) \), and \( \vec{C}^{n+\theta} = \vec{C} \left( \vec{u}^{n+\theta} \right) \). We have chosen in our computation \( \theta = 0 \). For this value, the fractional nodal velocities \( \vec{u}^{n+1} \) can be explicitly computed from Eq. (32) by
\[
\vec{u}^{n+1} = \vec{u}^{n} - \Delta t \vec{M}^{-1} \left[ \vec{H}^{n} \vec{u}^{n} - \alpha \vec{G} \vec{p}^{n} + \vec{C}^{n} \vec{c}^{n} - \vec{f}^{n} \right],
\]  
(33)
where \( \vec{M} \) is the lumped diagonal form of \( \vec{M} \).

Step 2  Compute \( \vec{p}^{n+1} \) from Eq. (30) as
\[
\vec{p}^{n+1} = - \left[ \vec{L}^{n} + \frac{\Delta t}{\rho} \vec{L} \right]^{-1} \left[ \vec{G}^{T} \vec{u}^{n+1} - \alpha \frac{\Delta t}{\rho} \vec{L} \vec{p}^{n} + \vec{Q} \vec{\pi}^{n} \right].
\]  
(34)

Step 3  Compute \( \vec{u}^{n+1} \) explicitly from Eq. (28a) as
\[
\vec{u}^{n+1} = \vec{u}^{n+1} + \Delta t \vec{M}^{-1} \vec{G} \left( \vec{p}^{n+1} - \alpha \vec{p}^{n} \right).
\]  
(35)

Step 4  Compute \( \vec{c}^{n+1} \) explicitly from Eq. (29b) as
\[
\vec{c}^{n+1} = - \vec{M}^{-1} \vec{C}^{n+1} \vec{u}^{n+1}.
\]  
(36)

Step 5  Compute \( \vec{\pi}^{n+1} \) explicitly from Eq. (29c) as
\[
\vec{\pi}^{n+1} = - \vec{M}^{-1} \vec{Q}^{T} \vec{p}^{n+1}.
\]  
(37)
Above algorithm has improved stabilization properties versus the standard segregation methods due to the introduction of the Laplacian matrix $\hat{L}$ in Eq. (34) which emanates from the FIC stabilization terms.

The boundary conditions are applied as follows. No condition is applied in the computation of the fractional velocities $\tilde{u}^{n+1}$ in Eq. (33). The prescribed velocities at the boundary are applied when solving for $\tilde{u}^{n+1}$ in the step 3. The prescribed pressures at the boundary are imposed by making $\tilde{p}^{n}$ equal to the prescribed pressure values.

### 5 Stokes flow

The formulation for a Stokes flow can be readily obtained simply by neglecting the convective terms in the general Navier–Stokes formulation. Consequently, the convective stabilization terms and the convective projection variables are not required. Also the intrinsic time parameters $\tau_i$ take now the simpler form [see Eq. (12)]:

$$
\tau_i = \frac{3h_i h_j}{8\mu}.
$$

(38)
The resulting discretized system of equations can be written as [see Eqs. (29)]

\[
\begin{align*}
\dot{\mathbf{u}} + \mathbf{Ku} - \mathbf{Gp} &= \mathbf{f} \\
\mathbf{G}^T\mathbf{d} + \mathbf{Lp} + \mathbf{Q}\bar{\pi} &= 0 \\
\mathbf{Q}^T\mathbf{d} + \mathbf{M}\bar{\pi} &= 0.
\end{align*}
\]

(39)

The fractional step algorithm of the previous section can now be implemented. We note that convergence of the predictor-corrector scheme is now faster due to the absence of the non linear convective terms in the momentum equation. The steady-state form of Eqs. (39) can be expressed in matrix form as

\[
\begin{pmatrix}
\mathbf{K} & -\mathbf{G} & 0 \\
-\mathbf{G}^T & -\mathbf{L} & -\mathbf{Q} \\
0 & -\mathbf{Q}^T & -\mathbf{M}
\end{pmatrix}
\begin{pmatrix}
\bar{\mathbf{u}} \\
\bar{\mathbf{p}} \\
\bar{\pi}
\end{pmatrix}
= \begin{pmatrix}
\mathbf{f} \\
0 \\
0
\end{pmatrix}.
\]

(40)

The system is symmetric and always positive definite and therefore leads to a non singular solution. This property holds for any interpolation function chosen for \( \bar{\mathbf{u}}, \bar{\mathbf{p}} \) and \( \bar{\pi} \), therefore overcoming the Babuška-Brezzi (BB) restrictions [1].

A reduced velocity-pressure formulation can be obtained by eliminating the pressure gradient projection variables \( \bar{\pi} \).
from the last equation to give
\[
\begin{bmatrix}
K - G \\
G \mathbf{T} \left( \mathbf{L} - Q \mathbf{M}^{-1} \mathbf{Q} \mathbf{T} \right)
\end{bmatrix}
\begin{bmatrix}
\mathbf{u} \\
\mathbf{p}
\end{bmatrix} = \begin{bmatrix}
f \\
0
\end{bmatrix}.
\]  
\tag{41}

The reduction process is simplified by using a diagonal form of matrix \( \mathbf{M} \). Applications of this scheme to incompressible solid mechanics problems are reported in [52,53].

6 Computation of the characteristic distances

The computation of the stabilization parameters is a crucial issue as they affect both the stability and accuracy of the numerical solution. The different procedures to compute the stabilization parameters are typically based on the study of simplified forms of the stabilized equations. Contributions to this topic are reported in [11–20, 26–31, 34, 45, 54, 55]. Despite the relevance of the problem there still lacks a general method to compute the stabilization parameters for all the range of flow situations.

Recent work of the authors in the application of the FIC/FEM formulation to convection-diffusion problems with sharp arbitrary gradients [39,41] has shown that the stabilizing FIC terms take the form of a simple orthotropic diffusion if the balance equation is written in the principal curvature directions of the solution. Excellent results were reported in [39,41] by computing first the characteristic length distances along the principal curvature directions, followed by a standard transformation of the distances to global axes. The resulting stabilized finite element equations capture the high gradient zones in the vicinity of the domain edges (boundary layers) as well as the sharp gradients appearing randomly in the interior of the domain [39,41]. The FIC/FEM thus reproduces the best features of both the so-called transverse (cross-wind) dissipation or shock capturing methods [56,57].

The numerical computations are simplified without apparent loss of accuracy if the main principal curvature direction of the solution at each element point is approximated by the direction of the gradient vector at the element center. The second principal direction (for 2D problems) is taken in the orthogonal direction to the gradient. For linear triangles and quadrilaterals these directions are assumed to be constant within the element [39,41].

Above simple scheme has been extended in this work for the computation of the characteristic distances \( h_{ij} \) for the momentum equations. As for the length parameters \( h_i \) in the mass conservation equation, the simplest assumption \( h_i = h_{ii} \) has been taken. Details of the algorithm for computing \( h_{ij} \) are given next (the method is explained for 2D problems although it is readily extensible to 3D problems).

For the \( i \)-th momentum balance equation and every step of the fractional step method described in Sect. 4:

1. A coordinate system \( \tilde{\xi}_1 \), \( \tilde{\xi}_2 \) is defined at each element point such that \( \tilde{\xi}_1 \) is aligned with the gradient of \( u_i \left( \tilde{\xi}_1 = \nabla^* u_i \right) \) and \( \tilde{\xi}_2 \) is orthogonal to \( \tilde{\xi}_1 \) in anticlockwise sense (Fig. 1). The angle that \( \tilde{\xi}_1 \) forms with the global \( \chi_1 \) axis is defined as \( \alpha_i \). Recall that the upper and lower index \( i \) denotes the \( i \)-th momentum equation.

2. The element characteristic distances \( h_{11} \) and \( h_{12} \) are defined as the maximum projections of the element sides along the \( \tilde{\xi}_1 \) and \( \tilde{\xi}_2 \) axes, respectively (Fig. 2).

3. The characteristic distances \( h_{11} \) and \( h_{12} \) are computed as
\[
\begin{bmatrix}
h_{11} \\
h_{12}
\end{bmatrix} = \begin{bmatrix} c_i & -s_i \\ s_i & c_i \end{bmatrix} \begin{bmatrix}
h_{11} \end{bmatrix}, \quad i = 1,2,
\]  
\tag{42}

with \( \cos \gamma_{ij} = \frac{c_i}{h_{ij}} \) and the local distances \( \tilde{h}_{11} \) and \( \tilde{h}_{12} \) are
\[
\tilde{h}_{11} = \left( \cot \tilde{\gamma}_{ij} - \frac{1}{\tilde{\gamma}_{ij}} \right) h_{11}, \quad \tilde{\gamma}_{ij} = \frac{\tilde{u}_{ij}}{2\mu}, \quad j = 1,2,
\]  
\tag{43}

where \( \tilde{u}_1 \) and \( \tilde{u}_2 \) are the components of the velocity vector along the local axes \( \tilde{\xi}_1 \) and \( \tilde{\xi}_2 \), respectively (Fig. 1).

7 Examples

The examples were solved with the Tdyn code where the formulation here presented has been implemented. The Tdyn code can be downloaded from the webpage given in [58].

7.1 Backward facing step at high Reynolds number

Figure 3 shows the geometry of the standard backward facing step problem. The boundary conditions were the following: \( u_1 = 1 \) and \( u_2 = 0 \) were taken at the entry while \( p = 0 \) was assumed at the exit. Slipping conditions were assumed

Comparison of the FIC/FEM result with experimental data and with numerical results obtained using different turbulence models.

Other results reported in the literature obtained using $K$-$\varepsilon$ and $K$-tau turbulence models [60–63]. We note again that the FIC/FEM formulation does not include any additional turbulence terms.

at the rest of the vertical and horizontal walls. A value of the kinematic viscosity $\nu = (\mu/\rho) = 2.1 \times 10^{-5}$ was taken giving a Reynolds number of $Re = (u_{\text{free}}H)/\nu = 47,619$ for $H = 1$ and $u_{\text{free}} = 1$.

Figure 3 also shows the relatively coarse mesh chosen of 30,850 three-noded triangular elements and 15,426 nodes. The contours of the horizontal and vertical velocities and details of the velocity vectors are shown in Figs. 4 and 5, respectively. Figure 6 shows the distribution of the horizontal velocity along the bottom line starting from the vertical wall of the step. The point where the horizontal velocity changes sign indicates the end of the recirculation area.

The length of the circulation area computed from Fig. 6 is 6.79. This value compares very well (3.2%) with the experimental value reported by Kim et al. [59] (see Table 1). The FIC/FEM results are remarkably accurate in comparison with other results reported in the literature obtained using $K$-$\varepsilon$ and $K$-tau turbulence models [60–63]. We note again that the FIC/FEM formulation does not include any additional turbulence terms.
7.2 Flow past a cylinder. Computation of the Strouhal instability

Figure 7 shows the geometry for the analysis of the flow past a cylinder of unit diameter ($D$). A unit horizontal velocity is prescribed at the inlet boundary and at the two horizontal walls. Zero pressure is prescribed at the outlet boundary. The dimensions of the analysis domain are $36 \times 27$ units. The origin of the coordinate system has been sampled at the center of the cylinder located at a distance of 13.1 units from the entry wall. Zero velocity is prescribed at the cylinder wall. The kinematic viscosity is $\nu = 0.01$. Figure 8 shows the mesh of 91,316 three-noded elements used for the computation. A detail of the mesh in the vicinity of the cylinder is also shown in Fig. 8.

The problem has been analyzed first for a value of the horizontal velocity at the entry of $u_1 = 1$ giving a Reynolds number of $Re = 100$. Figures 9 and 10, respectively, show the velocity modulus contours and the velocity vectors for $t = 100$ s.

Figure 11 shows images of the trajectory of a substance over a band of 2.45 units transported at the entry across the flow for $t = 100$ s. The picture shows clearly the oscillatory nature of the flow.

Figure 12 shows the oscillations of the horizontal velocity at the point $A$ with coordinates $(6.7, -1.02)$ with time. The Strouhal number computed from the shedding frequency $n$ as $S = (nD/|u|)$ is $S = 0.1702$. This number compares very well with the experimental result available in the literature (see Fig. 13).

The same problem was analyzed for a value of the kinematic viscosity $\nu = 0.001$ giving $Re = 1,000$. The same mesh of 91,316 linear triangles of Fig. 7 was used.

Figures 14, 15, 16 show, respectively, the velocity modulus contours, the velocity vectors in the vicinity of the cylinder for $t = 100$ s, and the trajectories of a substance transported across the flow. Figure 17 finally shows the oscillations of the horizontal velocity at point $A$. The computed value of the Strouhal number in this case was $S = 0.2103$. This value again coincides well with the reported experimental data (see Fig. 13).

It is a well known fact that for $Re > 300$ the flow past a cylinder exhibits 3D features. In [64] results from 2D and 3D computation were compared for $Re = 300$ and 800. While 3D features were observed even at $Re = 300$ and more so at $Re = 800$, there were no large discrepancies between the global flow parameters (such as drag, lift and Strouhal number) obtained from 2D and 3D computations. These conclusions justify the results of the 2D computations presented in the paper.

8 Conclusions

The finite calculus (FIC) form of the fluid mechanics equations is a good starting point for deriving stabilized FEM for solving a variety of incompressible fluid flow problems. The matrix stabilization terms introduced by the FIC formulation here presented allow to obtain physically sound solutions in the presence of sharp gradients occurring for high Reynolds numbers without the need of introducing a turbulence model. Good numerical solutions have been obtained in the 2D examples solved with relatively coarse meshes for moderate and high values of the Reynolds number. These preliminary results reinforce our idea that the stabilization terms introduced by the FIC formulation suffice to provide
good results for problems for which turbulence models are required using alternative numerical methods. These results also confirm the close link between the stabilized methods and turbulence models, which surely will be the object of much research in the near future.

Appendix

The FIC momentum equations in two dimensions (2D) are obtained by expressing the balance of momentum along the horizontal and vertical directions in the finite domains shown in Figs. 18 and 19, respectively.

The balance equation is written for each finite domain as

$$\sum f_i d\Omega = \frac{\partial}{\partial t} \int_\Omega \rho u_i d\Omega + \int_\Gamma (\rho u_i) u^T n d\Gamma \quad i = 1, 2, \quad (44)$$

where $f_i$ includes the forces due to the stresses acting on the boundary of the balance domain and the body forces per unit area (Figs. 18, 19).

Expressing the values of the momentum and force terms at the end point of the balance domain in terms the values at an arbitrary point (such as the corner point A) using higher order Taylor expansions and retaining second order terms gives after
FIC/FEM formulation with matrix stabilizing terms for incompressible flows at low and high Reynolds numbers

Fig. 17 Flow past a cylinder, Re = 1,000. Oscillations with time of the horizontal velocity at the point with coordinates A (6.7 − 1.02)

Fig. 18 Finite domain where balance of momentum is imposed along the horizontal direction

some algebra [32] the FIC momentum equations along the i-th coordinate direction as

\[ r_i - \frac{1}{2} h_{ij} \frac{\partial r_j}{\partial x_j} = 0 \quad i, j = 1, 2 \]  (45)

with

\[ r_i := \rho \left( \frac{\partial u_i}{\partial t} + u_j \frac{\partial u_i}{\partial x_j} \right) - \partial \sigma_{ij} \frac{\partial}{\partial x_j} - b_i \]  (46)

with \( \sigma_{ij} = s_{ij} - p \delta_{ij} \) where \( s_{ij} \) and \( p \) are the deviatoric stresses and the pressure, respectively.

Note that distance \( h_{12} \) is arbitrary when writing the balance of momentum along the \( x_1 \) direction. The same applies for the distance \( h_{21} \) when deriving the balance equation along the \( x_2 \) direction. Thus, in general, \( h_{12} \neq h_{21} \) and this explains the matrix form of the FIC momentum equations.

The FIC mass balance equation is obtained by invoking the balance of mass in the finite domain of Fig. 20

\[ \int_{\Gamma} \rho u^T n d\Gamma = 0. \]  (47)

Expanding the values of \( \rho u_i \) at the corner points in terms of the value at an arbitrary point gives of the mass balance domain the FIC mass balance equation as [32, 43]

\[ \frac{\partial u_i}{\partial x_i} - \frac{1}{2} h_{ij} \frac{\partial}{\partial x_j} \left( \frac{\partial u_i}{\partial x_j} \right) = 0. \]

Note that a matrix form of the characteristic distances is not obtained in this case as the mass balance equation expresses the conservation of the mass in the whole domain ABCD of Fig. 20 with dimensions \( h_1 \) and \( h_2 \). Distances \( h_1 \) and \( h_2 \) should be taken in general different from distances \( h_{ij} \) defining the domain where balance of momentum is enforced. In our computations we have however assumed that \( h_1 = h_{11} \) and \( h_2 = h_{22} \) for simplicity.
